## Training of DDPM

- 1. Get the sample  $\mathbf{x}_0 \sim \pi(\mathbf{x})$ .
- 2. Sample timestamp  $t \sim U\{1, T\}$  and the noise  $\epsilon \sim \mathcal{N}(0, I)$ .
- 3. Get noisy image  $\mathbf{x}_t = \sqrt{\bar{\alpha}_t} \cdot \mathbf{x}_0 + \sqrt{1 \bar{\alpha}_t} \cdot \epsilon$ .
- 4. Compute loss  $\mathcal{L}_{\text{simple}} = \|\epsilon \epsilon_{\theta,t}(\mathbf{x}_t)\|^2$ .

# Sampling of DDPM

- 1. Sample  $\mathbf{x}_T \sim \mathcal{N}(0, \mathbf{I})$ .
- 2. Compute mean of  $p(\mathbf{x}_{t-1}|\mathbf{x}_t, \boldsymbol{\theta}) = \mathcal{N}(\boldsymbol{\mu}_{\boldsymbol{\theta},t}(\mathbf{x}_t), \sigma_t^2 \cdot \mathbf{I})$ :

$$\mu_{\theta,t}(\mathbf{x}_t) = \frac{1}{\sqrt{\alpha_t}} \cdot \mathbf{x}_t - \frac{1 - \alpha_t}{\sqrt{\alpha_t(1 - \bar{\alpha}_t)}} \cdot \epsilon_{\theta,t}(\mathbf{x}_t)$$

3. Get denoised image  $\mathbf{x}_{t-1} = \boldsymbol{\mu}_{\theta,t}(\mathbf{x}_t) + \sigma_t \cdot \boldsymbol{\epsilon}$ , where  $\boldsymbol{\epsilon} \sim \mathcal{N}(0, \mathbf{I})$ .

# DDPM objective

$$\mathbb{E}_{\pi(\mathbf{x}_0)} \mathbb{E}_{t \sim U\{1, T\}} \mathbb{E}_{q(\mathbf{x}_t | \mathbf{x}_0)} \left[ \frac{(1 - \alpha_t)^2}{2\tilde{\beta}_t \alpha_t} \left\| \mathbf{s}_{\theta, t}(\mathbf{x}_t) - \nabla_{\mathbf{x}_t} \log q(\mathbf{x}_t | \mathbf{x}_0) \right\|_2^2 \right]$$

In practice the coefficient is omitted.

#### NCSN objective

$$\mathbb{E}_{\pi(\mathbf{x}_0)} \mathbb{E}_{t \sim U\{1,T\}} \mathbb{E}_{q(\mathbf{x}_t|\mathbf{x}_0)} \big\| \mathbf{s}_{\boldsymbol{\theta},\sigma_t}(\mathbf{x}_t) - \nabla_{\mathbf{x}_t} \log q(\mathbf{x}_t|\mathbf{x}_0) \big\|_2^2$$

**Note:** The objective of DDPM and NCSN is almost identical. But the difference in sampling scheme:

- NCSN uses annealed Langevin dynamics;
- DDPM uses ancestral sampling.

$$\mathbf{s}_{\boldsymbol{\theta},t}(\mathbf{x}_t) = -\frac{\boldsymbol{\epsilon}_{\boldsymbol{\theta},t}(\mathbf{x}_t)}{\sqrt{1-\bar{\alpha}_t}} = \nabla_{\mathbf{x}_t} \log p(\mathbf{x}_t|\boldsymbol{\theta})$$

Unconditional generation

$$\mathbf{x}_{t-1} = rac{1}{\sqrt{lpha_t}} \cdot \mathbf{x}_t + rac{1-lpha_t}{\sqrt{lpha_t}} \cdot 
abla_{\mathbf{x}_t} \log p(\mathbf{x}_t|oldsymbol{ heta}) + \sigma_t \cdot oldsymbol{\epsilon}$$

Conditional generation

$$\mathbf{x}_{t-1} = \frac{1}{\sqrt{\alpha_t}} \cdot \mathbf{x}_t + \frac{1 - \alpha_t}{\sqrt{\alpha_t}} \cdot \nabla_{\mathbf{x}_t} \log p(\mathbf{x}_t | \mathbf{y}, \boldsymbol{\theta}) + \sigma_t \cdot \boldsymbol{\epsilon}$$

Conditional distribution

$$\nabla_{\mathbf{x}_t} \log p(\mathbf{x}_t | \mathbf{y}, \boldsymbol{\theta}) = \nabla_{\mathbf{x}_t} \log p(\mathbf{y} | \mathbf{x}_t) - \frac{\epsilon_{\boldsymbol{\theta}, t}(\mathbf{x}_t)}{\sqrt{1 - \bar{\alpha}_t}}$$

Here  $p(\mathbf{y}|\mathbf{x}_t)$  – classifier on noisy samples (we have to learn it separately).

Classifier-corrected noise prediction

$$\epsilon_{\theta,t}(\mathbf{x}_t, \mathbf{y}) = \epsilon_{\theta,t}(\mathbf{x}_t) - \sqrt{1 - \bar{\alpha}_t} \cdot \nabla_{\mathbf{x}_t} \log p(\mathbf{y}|\mathbf{x}_t)$$

#### Guidance scale

$$\epsilon_{\theta,t}(\mathbf{x}_t, \mathbf{y}) = \epsilon_{\theta,t}(\mathbf{x}_t) - \gamma \cdot \sqrt{1 - \bar{\alpha}_t} \cdot \nabla_{\mathbf{x}_t} \log p(\mathbf{y}|\mathbf{x}_t)$$
$$\nabla_{\mathbf{x}_t}^{\gamma} \log p(\mathbf{x}_t|\mathbf{y}, \theta) = \nabla_{\mathbf{x}_t} \log \left(\frac{p(\mathbf{y}|\mathbf{x}_t)^{\gamma} p(\mathbf{x}_t|\theta)}{Z}\right)$$

**Note:** Guidance scale  $\gamma$  tries to sharpen the distribution  $p(\mathbf{y}|\mathbf{x}_t)$ .

# Guided sampling

$$\begin{aligned} \boldsymbol{\epsilon}_{\boldsymbol{\theta},t}(\mathbf{x}_t,\mathbf{y}) &= \boldsymbol{\epsilon}_{\boldsymbol{\theta},t}(\mathbf{x}_t) - \gamma \cdot \sqrt{1 - \bar{\alpha}_t} \cdot \nabla_{\mathbf{x}_t} \log p(\mathbf{y}|\mathbf{x}_t) \\ \boldsymbol{\mu}_{\boldsymbol{\theta},t}(\mathbf{x}_t,\mathbf{y}) &= \frac{1}{\sqrt{\alpha_t}} \mathbf{x}_t - \frac{1 - \alpha_t}{\sqrt{\alpha_t(1 - \bar{\alpha}_t)}} \cdot \boldsymbol{\epsilon}_{\boldsymbol{\theta},t}(\mathbf{x}_t,\mathbf{y}) \\ \mathbf{x}_{t-1} &= \boldsymbol{\mu}_{\boldsymbol{\theta},t}(\mathbf{x}_t,\mathbf{y}) + \sigma_t \cdot \boldsymbol{\epsilon}, \quad \boldsymbol{\epsilon} \sim \mathcal{N}(\mathbf{0},\mathbf{I}) \end{aligned}$$

- Previous method requires training the additional classifier model  $p(\mathbf{y}|\mathbf{x}_t)$  on the noisy data.
- Let try to avoid this requirement.

$$\nabla_{\mathbf{x}_t} \log p(\mathbf{y}|\mathbf{x}_t) = \nabla_{\mathbf{x}_t} \log p(\mathbf{x}_t|\mathbf{y}, \boldsymbol{\theta}) - \nabla_{\mathbf{x}_t} \log p(\mathbf{x}_t|\boldsymbol{\theta})$$

$$\begin{split} \nabla_{\mathbf{x}_t}^{\gamma} \log p(\mathbf{x}_t|\mathbf{y}, \boldsymbol{\theta}) &= \nabla_{\mathbf{x}_t} \log p(\mathbf{x}_t|\boldsymbol{\theta}) + \gamma \cdot \nabla_{\mathbf{x}_t} \log p(\mathbf{y}|\mathbf{x}_t) = \\ &= (1 - \gamma) \cdot \nabla_{\mathbf{x}_t} \log p(\mathbf{x}_t|\boldsymbol{\theta}) + \gamma \cdot \nabla_{\mathbf{x}_t} \log p(\mathbf{x}_t|\mathbf{y}, \boldsymbol{\theta}) \end{split}$$

#### Classifier-free-corrected noise prediction

$$\hat{\boldsymbol{\epsilon}}_{\boldsymbol{\theta},t}(\mathbf{x}_t,\mathbf{y}) = \gamma \cdot \boldsymbol{\epsilon}_{\boldsymbol{\theta},t}(\mathbf{x}_t,\mathbf{y}) + (1-\gamma) \cdot \boldsymbol{\epsilon}_{\boldsymbol{\theta},t}(\mathbf{x}_t)$$

- ► Train the single model  $\epsilon_{\theta,t}(\mathbf{x}_t,\mathbf{y})$  on **supervised** data alternating with real conditioning  $\mathbf{y}$  and empty conditioning  $\mathbf{y} = \emptyset$ .
- ▶ Apply the model twice during inference.

# Continuous-in-time dynamic (neural ODE)

$$egin{aligned} rac{d\mathbf{z}(t)}{dt} &= \mathbf{f}_{m{ heta}}(\mathbf{z}(t),t); \quad ext{with initial condition } \mathbf{z}(t_0) = \mathbf{z}_0. \ \mathbf{z}(t_1) &= \int_{t_0}^{t_1} \mathbf{f}_{m{ heta}}(\mathbf{z}(t),t) dt + \mathbf{z}_0 pprox ext{ODESolve}(\mathbf{z}(t_0),\mathbf{f}_{m{ heta}},t_0,t_1). \end{aligned}$$

#### Euler update step

$$\frac{\mathbf{z}(t+\Delta t)-\mathbf{z}(t)}{\Delta t}=\mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t),t) \ \Rightarrow \ \mathbf{z}(t+\Delta t)=\mathbf{z}(t)+\Delta t \cdot \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t),t)$$

# Theorem (Picard)

If  ${\bf f}$  is uniformly Lipschitz continuous in  ${\bf z}$  and continuous in t, then the ODE has a **unique** solution.

$$\mathbf{z} = \mathbf{z}(t_1) = \mathbf{z}(t_0) + \int_{t_0}^{t_1} \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t) dt$$
 $\mathbf{z} = \mathbf{z}(t_0) = \mathbf{z}(t_1) + \int_{t_1}^{t_0} \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t) dt$

# Continuous-in-time Normalizing Flows

#### What do we need?

- ▶ We need the way to compute  $p(\mathbf{z}, t)$  at any moment t.
- We need the way to find the optimal parameters  $\theta$  of the dynamic  $\mathbf{f}_{\theta}$ .

# Theorem (Kolmogorov-Fokker-Planck: special case)

If f is uniformly Lipschitz continuous in z and continuous in t, then

$$\frac{d \log p(\mathbf{z}(t), t)}{dt} = -\operatorname{tr}\left(\frac{\partial \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t)}{\partial \mathbf{z}(t)}\right).$$

$$\log p(\mathbf{z}(t_1), t_1) = \log p(\mathbf{z}(t_0), t_0) - \int_{t_0}^{t_1} \operatorname{tr} \left( \frac{\partial \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t)}{\partial \mathbf{z}(t)} \right) dt.$$

It means that if we have the value  $\mathbf{z}_0 = \mathbf{z}(t_0)$  then the solution of the ODE will give us the density at the moment  $t_1$ .

# Continuous-in-time Normalizing Flows

Forward transform + log-density

$$\mathbf{x} = \mathbf{z} + \int_{t_0}^{t_1} \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t) dt$$

$$\log p(\mathbf{x}|\boldsymbol{\theta}) = \log p(\mathbf{z}) - \int_{t_0}^{t_1} \operatorname{tr}\left(\frac{\partial \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t)}{\partial \mathbf{z}(t)}\right) dt$$

Here  $p(\mathbf{x}|\theta) = p(\mathbf{z}(t_1), t_1), \ p(\mathbf{z}) = p(\mathbf{z}(t_0), t_0).$ 

- ▶ **Discrete-in-time NF**: evaluation of determinant of the Jacobian costs  $O(m^3)$  (we need invertible  $\mathbf{f}$ ).
- **Continuous-in-time NF**: getting the trace of the Jacobian costs  $O(m^2)$  (we need smooth **f**).

# Why $O(m^2)$ ?

 $\operatorname{tr}\left(\frac{\partial f_{\boldsymbol{\theta}}(\mathbf{z}(t))}{\partial \mathbf{z}(t)}\right)$  costs  $O(m^2)$  (m evaluations of  $\mathbf{f}$ ), since we have to compute a derivative for each diagonal element. It is possible to reduce cost from  $O(m^2)$  to O(m)!

## Outline

- 1. Kolmogorov-Fokker-Planck equation for NF log-likelihood
- 2. FFJORD (Hutchinson's trace estimator)

Adjoint method for continuous-in-time NF

4. SDE basics

# Continuous-in-time Normalizing Flows

#### Hutchinson's trace estimator

If  $\epsilon \in \mathbb{R}^m$  is a random variable with  $\mathbb{E}[\epsilon] = 0$  and  $\mathsf{cov}(\epsilon) = \mathbf{I}$ , then

$$\operatorname{tr}(\mathbf{A}) = \operatorname{tr}(\mathbf{A} \cdot \mathbf{I}) = \operatorname{tr}\left(\mathbf{A} \cdot \mathbb{E}_{p(\epsilon)} \left[\epsilon \epsilon^{T}\right]\right) =$$

$$= \mathbb{E}_{p(\epsilon)} \left[\operatorname{tr}\left(\mathbf{A} \epsilon \epsilon^{T}\right)\right] = \mathbb{E}_{p(\epsilon)} \left[\epsilon^{T} \mathbf{A} \epsilon\right]$$

Jacobian vector products  $\mathbf{v}^T \frac{\partial f}{\partial \mathbf{z}}$  can be computed for approximately the same cost as evaluating  $\mathbf{f}$  (torch.autograd.functional.jvp).

# FFJORD density estimation

$$\log p(\mathbf{z}(t_1)) = \log p(\mathbf{z}(t_0)) - \int_{t_0}^{t_1} \operatorname{tr}\left(\frac{\partial \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t)}{\partial \mathbf{z}(t)}\right) dt =$$

$$= \log p(\mathbf{z}(t_0)) - \mathbb{E}_{p(\epsilon)} \int_{t_0}^{t_1} \left[\epsilon^{T} \frac{\partial \mathbf{f}}{\partial \mathbf{z}} \epsilon\right] dt.$$

Grathwohl W. et al. FFJORD: Free-form Continuous Dynamics for Scalable Reversible Generative Models. 2018

## Outline

- 1. Kolmogorov-Fokker-Planck equation for NF log-likelihood
- 2. FFJORD (Hutchinson's trace estimator)

3. Adjoint method for continuous-in-time NF

4. SDE basics

#### Neural ODE

#### Continuous-in-time NF

$$\begin{split} \frac{d\mathbf{z}(t)}{dt} &= \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t) & \frac{d \log p(\mathbf{z}(t), t)}{dt} = -\mathrm{tr}\left(\frac{\partial \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t)}{\partial \mathbf{z}(t)}\right) \\ \mathbf{x} &= \mathbf{z} + \int_{t_0}^{t_1} \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t) dt & \log p(\mathbf{x}|\boldsymbol{\theta}) = \log p(\mathbf{z}) - \int_{t_0}^{t_1} \mathrm{tr}\left(\frac{\partial \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t)}{\partial \mathbf{z}(t)}\right) dt \end{split}$$

How to get optimal parameters of  $\theta$ ?

For fitting parameters we need gradients. We need the analogue of the backpropagation.

# Forward pass (Loss function)

$$\mathbf{z} = \mathbf{x} + \int_{t_1}^{t_0} \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t) dt, \quad L(\mathbf{z}) = -\log p(\mathbf{x}|\boldsymbol{\theta})$$
 $L(\mathbf{z}) = -\log p(\mathbf{z}) + \int_{t_0}^{t_1} \operatorname{tr}\left(\frac{\partial \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t)}{\partial \mathbf{z}(t)}\right) dt$ 

#### Neural ODE

## Adjoint functions

$$\mathbf{a_z}(t) = \frac{\partial L}{\partial \mathbf{z}(t)}; \quad \mathbf{a_{\theta}}(t) = \frac{\partial L}{\partial \boldsymbol{\theta}(t)}.$$

These functions show how the gradient of the loss depends on the hidden state  $\mathbf{z}(t)$  and parameters  $\theta$ .

Theorem (Pontryagin)

$$\frac{d\mathbf{a}_{\mathbf{z}}(t)}{dt} = -\mathbf{a}_{\mathbf{z}}(t)^{\mathsf{T}} \cdot \frac{\partial \mathbf{f}_{\theta}(\mathbf{z}(t), t)}{\partial \mathbf{z}}; \quad \frac{d\mathbf{a}_{\theta}(t)}{dt} = -\mathbf{a}_{\mathbf{z}}(t)^{\mathsf{T}} \cdot \frac{\partial \mathbf{f}_{\theta}(\mathbf{z}(t), t)}{\partial \theta}.$$

Solution for adjoint function

$$\begin{split} \frac{\partial L}{\partial \boldsymbol{\theta}(t_1)} &= \mathbf{a}_{\boldsymbol{\theta}}(t_1) = -\int_{t_0}^{t_1} \mathbf{a}_{\mathbf{z}}(t)^T \frac{\partial \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t)}{\partial \boldsymbol{\theta}(t)} dt + 0 \\ \frac{\partial L}{\partial \mathbf{z}(t_1)} &= \mathbf{a}_{\mathbf{z}}(t_1) = -\int_{t_0}^{t_1} \mathbf{a}_{\mathbf{z}}(t)^T \frac{\partial \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t)}{\partial \mathbf{z}(t)} dt + \frac{\partial L}{\partial \mathbf{z}(t_0)} \end{split}$$

**Note:** These equations are solved in reverse time direction.

# Adjoint method

## Forward pass

$$\mathbf{z} = \mathbf{z}(t_0) = \int_{t_0}^{t_1} \mathbf{f}_{m{ heta}}(\mathbf{z}(t),t) dt + \mathbf{x} \quad \Rightarrow \quad \mathsf{ODE} \; \mathsf{Solver}$$

## Backward pass

$$\begin{split} &\frac{\partial L}{\partial \boldsymbol{\theta}(t_1)} = \boldsymbol{a}_{\boldsymbol{\theta}}(t_1) = -\int_{t_0}^{t_1} \boldsymbol{a}_{\boldsymbol{z}}(t)^T \frac{\partial f_{\boldsymbol{\theta}}(\boldsymbol{z}(t),t)}{\partial \boldsymbol{\theta}(t)} dt + 0 \\ &\frac{\partial L}{\partial \boldsymbol{z}(t_1)} = \boldsymbol{a}_{\boldsymbol{z}}(t_1) = -\int_{t_0}^{t_1} \boldsymbol{a}_{\boldsymbol{z}}(t)^T \frac{\partial f_{\boldsymbol{\theta}}(\boldsymbol{z}(t),t)}{\partial \boldsymbol{z}(t)} dt + \frac{\partial L}{\partial \boldsymbol{z}(t_0)} \\ &\boldsymbol{z}(t_1) = -\int_{t_1}^{t_0} f_{\boldsymbol{\theta}}(\boldsymbol{z}(t),t) dt + \boldsymbol{z}_0. \end{split} \right\} \Rightarrow \mathsf{ODE} \; \mathsf{Solver}$$

**Note:** These scary formulas are the standard backprop in the discrete case.

## Outline

- 1. Kolmogorov-Fokker-Planck equation for NF log-likelihood
- 2. FFJORD (Hutchinson's trace estimator)

3. Adjoint method for continuous-in-time NF

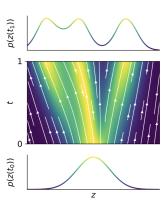

4. SDE basics

# Ordinary differential equation (ODE)

## Continuous-in-time Normalizing Flows

$$\frac{d\mathbf{z}(t)}{dt} = \mathbf{f}_{\theta}(\mathbf{z}(t), t);$$
 with initial condition  $\mathbf{z}(t_0) = \mathbf{z}_0$ 

- Let  $z(t_0)$  will be a random variable with some density function  $p(z(t_0))$ .
- ► Then  $\mathbf{z}(t_1)$  will be also a random variable with some other density function  $p(\mathbf{z}(t_1))$ .
- We could say that we have the joint density function p(z(t), t).
- What is the difference between p(z(t), t) and p(z, t)?

# Ordinary differential equation (ODE)

$$d\mathbf{z} = \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}, t) \cdot dt$$

Discretization of ODE (Euler method)

$$\mathbf{z}(t+dt) = \mathbf{z}(t) + \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t),t) \cdot dt$$

Theorem (Kolmogorov-Fokker-Planck: special case)

If f is uniformly Lipschitz continuous in z and continuous in t, then

$$\frac{d \log p(\mathbf{z}(t), t)}{dt} = -\operatorname{tr}\left(\frac{\partial \mathbf{f}_{\boldsymbol{\theta}}(\mathbf{z}(t), t)}{\partial \mathbf{z}(t)}\right).$$

It means that if we have the value  $\mathbf{z}_0 = \mathbf{z}(t_0)$  then the solution of the ODE will give us the density at the moment  $t_1$ .

Let define stochastic process  $\mathbf{x}(t)$  with initial condition  $\mathbf{x}(0) \sim p_0(\mathbf{x}) = \pi(\mathbf{x})$ :

$$d\mathbf{x} = \mathbf{f}(\mathbf{x}, t)dt + g(t)d\mathbf{w}$$

- ▶  $\mathbf{f}(\mathbf{x},t): \mathbb{R}^m \times [0,1] \to \mathbb{R}^m$  is the **drift** function of  $\mathbf{x}(t)$ .
- ▶  $g(t) : \mathbb{R} \to \mathbb{R}$  is the **diffusion** function of  $\mathbf{x}(t)$ .
- $\mathbf{w}(t)$  is the standard Wiener process (Brownian motion):
  - 1.  $\mathbf{w}(0) = 0$  (almost surely);
  - 2.  $\mathbf{w}(t)$  has independent increments;
  - 3.  $\mathbf{w}(t) \mathbf{w}(s) \sim \mathcal{N}(0, (t-s)\mathbf{I})$ , for t > s.
- $\mathbf{w} = \mathbf{w}(t + dt) \mathbf{w}(t) = \mathcal{N}(0, \mathbf{l} \cdot dt) = \epsilon \cdot \sqrt{dt}$ , where  $\epsilon \sim \mathcal{N}(0, \mathbf{l})$ .
- ▶ If g(t) = 0 we get standard ODE.

$$d\mathbf{x} = \mathbf{f}(\mathbf{x}, t)dt + g(t)d\mathbf{w}$$

- ▶ In contrast to ODE, initial condition x(0) does not uniquely determine the process trajectory.
- We have two sources of randomness: initial distribution  $p_0(\mathbf{x})$  and Wiener process  $\mathbf{w}(t)$ .

# Discretization of SDE (Euler method)

$$\mathbf{x}(t+dt) = \mathbf{x}(t) + \mathbf{f}(\mathbf{x}(t),t) \cdot dt + g(t) \cdot \epsilon \cdot \sqrt{dt}$$

If dt = 1, then

$$\mathbf{x}_{t+1} = \mathbf{x}_t + \mathbf{f}(\mathbf{x}_t, t) + g(t) \cdot \epsilon$$

- At each moment t we have the density  $p(\mathbf{x}(t), t)$ .
- $p: \mathbb{R}^m \times [0,1] \to \mathbb{R}_+$  is a **probability path** between  $p_0(\mathbf{x})$  and  $p_1(\mathbf{x})$ .
- ▶ How to get the distribution path  $p(\mathbf{x}, t)$  for  $\mathbf{x}(t)$ ?

$$d\mathbf{x} = \mathbf{f}(\mathbf{x}, t)dt + g(t)d\mathbf{w}, \quad d\mathbf{w} = \epsilon \cdot \sqrt{dt}, \quad \epsilon \sim \mathcal{N}(0, \mathbf{I}).$$

# Theorem (Kolmogorov-Fokker-Planck)

Evolution of the distribution  $p(\mathbf{x}, t)$  is given by the following equation:

$$\frac{\partial p(\mathbf{x},t)}{\partial t} = -\text{div}\left(\mathbf{f}(\mathbf{x},t)p(\mathbf{x},t)\right) + \frac{1}{2}g^2(t)\Delta_{\mathbf{x}}p(\mathbf{x},t)$$

Here

$$\operatorname{div}(\mathbf{v}) = \sum_{i=1}^{m} \frac{\partial v_i(\mathbf{x})}{\partial x_i} = \operatorname{tr}\left(\frac{\partial \mathbf{v}(\mathbf{x})}{\partial \mathbf{x}}\right)$$

$$\Delta_{\mathbf{x}} p(\mathbf{x}, t) = \sum_{i=1}^{m} \frac{\partial^{2} p(\mathbf{x}, t)}{\partial x_{i}^{2}} = \operatorname{tr} \left( \frac{\partial^{2} p(\mathbf{x}, t)}{\partial \mathbf{x}^{2}} \right)$$

$$\frac{\partial p(\mathbf{x},t)}{\partial t} = \operatorname{tr}\left(-\frac{\partial}{\partial \mathbf{x}}\big[\mathbf{f}(\mathbf{x},t)p(\mathbf{x},t)\big] + \frac{1}{2}g^2(t)\frac{\partial^2 p(\mathbf{x},t)}{\partial \mathbf{x}^2}\right)$$

Theorem (Kolmogorov-Fokker-Planck)

$$\frac{\partial p(\mathbf{x},t)}{\partial t} = \operatorname{tr}\left(-\frac{\partial}{\partial \mathbf{x}}\left[\mathbf{f}(\mathbf{x},t)p(\mathbf{x},t)\right] + \frac{1}{2}g^{2}(t)\frac{\partial^{2}p(\mathbf{x},t)}{\partial \mathbf{x}^{2}}\right)$$

- KFP theorem uniquely defines the SDE.
- This is the generalization of KFP theorem that we used in continuous-in-time NF:

$$\frac{d \log p(\mathbf{x}(t), t)}{dt} = -\operatorname{tr}\left(\frac{\partial \mathbf{f}(\mathbf{x}, t)}{\partial \mathbf{x}}\right).$$

Langevin SDE (special case)

$$d\mathbf{x} = \mathbf{f}(\mathbf{x}, t)dt + g(t)d\mathbf{w}$$
$$d\mathbf{x} = \frac{1}{2} \frac{\partial}{\partial \mathbf{x}} \log p(\mathbf{x}, t)dt + 1 \cdot d\mathbf{w}$$

Let apply KFP theorem to this SDE.

# Langevin SDE (special case)

$$d\mathbf{x} = \frac{1}{2} \frac{\partial}{\partial \mathbf{x}} \log p(\mathbf{x}, t) dt + 1 \cdot d\mathbf{w}$$

$$\begin{split} \frac{\partial p(\mathbf{x},t)}{\partial t} &= \operatorname{tr}\left(-\frac{\partial}{\partial \mathbf{x}}\left[p(\mathbf{x},t)\frac{1}{2}\frac{\partial}{\partial \mathbf{x}}\log p(\mathbf{x},t)\right] + \frac{1}{2}\frac{\partial^2 p(\mathbf{x},t)}{\partial \mathbf{x}^2}\right) = \\ &= \operatorname{tr}\left(-\frac{\partial}{\partial \mathbf{x}}\left[\frac{1}{2}\frac{\partial}{\partial \mathbf{x}}p(\mathbf{x},t)\right] + \frac{1}{2}\frac{\partial^2 p(\mathbf{x},t)}{\partial \mathbf{x}^2}\right) = 0 \end{split}$$

The density  $p(\mathbf{x}, t) = \text{const}(t)!$ If  $\mathbf{x}(0) \sim p_0(\mathbf{x})$ , then  $\mathbf{x}(t) \sim p_0(\mathbf{x})$ .

Discretized Langevin SDE

$$\mathbf{x}_{t+1} - \mathbf{x}_t = \frac{\eta}{2} \cdot \frac{\partial}{\partial \mathbf{x}} \log p(\mathbf{x}, t) + \sqrt{\eta} \cdot \epsilon, \quad \eta \approx dt.$$

Langevin dynamic

$$\mathbf{x}_{t+1} = \mathbf{x}_t + \frac{\eta}{2} \cdot \nabla_{\mathbf{x}} \log p(\mathbf{x}|\boldsymbol{\theta}) + \sqrt{\eta} \cdot \boldsymbol{\epsilon}, \quad \eta \approx dt.$$

# Summary

- Nolmogorov-Fokker-Planck theorem allows to calculate  $\log p(\mathbf{z}, t)$  at arbitrary moment t.
- FFJORD model makes such kind of NF scalable.
- SDE defines stochastic process with drift and diffusion terms. ODEs are the special case of SDEs.
- ► KFP equation defines the dynamic of the probability function for the SDE.
- Langevin SDE has constant probability path.
